

1G-Bit 3.3V NAND FLASH MEMORY

Descriptions

The H7A11G24B9CN (1G-bit) NAND Flash memory provides a storage solution for embedded systems with limited space, pins and power. It is ideal for code shadowing to RAM, solid state applications and storing media data such as, voice, video, text and photos. The device operates on a single 2.7V to 3.6V power supply with active current consumption as low as 25mA at 3V and 10uA for CMOS standby current.

The memory array totals 138,412,032 bytes, and organized into 1,024 erasable blocks of 135,168 bytes. Each block consists of 64 programmable pages of 2,112-bytes each. Each page consists of 2,048-bytes for the main data storage area and 64-bytes for the spare data area (The spare area is typically used for error management functions). The H7A11G24B9CN supports the standard NAND flash memory interface using the multiplexed 8-bit bus to transfer data, addresses, and command instructions.

The five control signals, CLE, ALE, #CE, #RE and #WE handle the bus interface protocol. Also, the device has two other signal pins, the #WP (Write Protect) and the RY/#BY (Ready/Busy) for monitoring the device status.

Features

• Basic Features

- Density : 1Gbit (Single chip solution)
- Vcc : 2.7V to 3.6V
- Bus width : x8
- Operating temperature
Commercial: 0°C to 70°C

• Single-Level Cell (SLC) technology.

• Organization

- Density: 1G-bit/128M-byte
- Page size
2,112 bytes (2048 + 64 bytes)
- Block size
64 pages (128K + 4K bytes)

• Highest Performance

- Read performance (Max.)
 - Random read: 25us
 - Sequential read cycle: 25ns
- Write Erase performance
 - Page program time: 250us(typ.)
 - Block erase time: 2ms(typ.)
- Endurance 100,000 Erase/Program Cycles
- 10-years data retention

• Command set

- Standard NAND command set
- Additional command support
 - Sequential / Random Cache Read
 - Cache Program
 - Copy Back
- OTP feature
- Block Lock feature

• Lowest power consumption

- Read: 25mA(typ.)
- Program/Erase: 25mA(typ.)
- CMOS standby: 10uA(typ.)

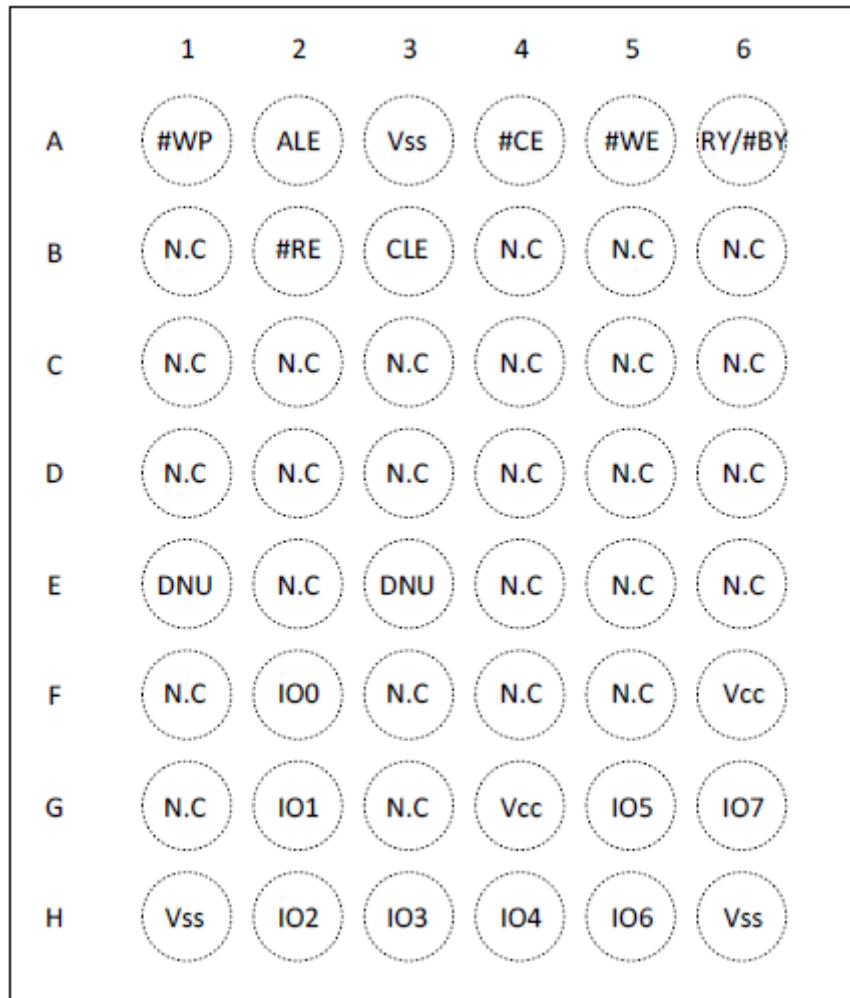

• Space Efficient Packaging

- 48-ball VFBGA

Absolute Maximum Rating(3.3V)

Item	Symbol	Conditions	Rating	Unit
Supply Voltage	V _{cc}		-0.6 ~ 4.6	V
Voltage Applied to Any Pin	V _{in}	Relative to Ground	-0.6 ~ 4.6	V
Storage Temperature	T _{STG}		-65 ~ 150	°C
Short circuit output current	I _{os}		5	mA

Note 1: Minimum DC voltage is -0.6V on input/output pins. During transitions, this level may undershoot to -2.0V for periods <30ns.

Note 2: Maximum DC voltage on input/output pins is Vcc+0.3V which, during transitions, may overshoot to Vcc+2.0V for periods <20ns.

Note 3: This device has been designed and tested for the specified operation ranges. Proper operation outside of these levels is not guaranteed. Exposure to absolute maximum ratings may affect device reliability. Exposure beyond absolute maximum ratings may cause permanent damage.

Device Power-up Timing

The device is designed to avoid unexpected program/erase operations during power transitions. When the device is powered on, the system has to wait until the ready state. #WP is recommended to VIL for preventing unexpected Program and Erase operations during power-transition until Vcc is stable. The RY/#BY will become valid after 50µs from the Vcc ramp start, and at least 10µs after Vcc reaches minimum Vcc level. The first command has to be a RESET command after the device is powered on. Before issuing RESET command, the system has to wait until the RY/#BY goes HIGH, or wait at least 100µs after Vcc reaches minimum Vcc. After issuing the RESET command, the busy time is 1ms maximum. RY/#BY polling or READ STATUS command can monitor the reset busy period. After completing this procedure, the device is initialized and ready for the operation (See Below Figure).

Invalid Block Management

The H7A11G24B9CN may have initial invalid blocks when it ships from factory. Also, additional invalid blocks may develop during the use of the device. Nvb represents the minimum number of valid blocks in the total number of available blocks(see below table). An invalid block is defined as blocks that contain one or more bad bits. Block 0, block address 00h is guaranteed to be a valid block at the time of shipment.

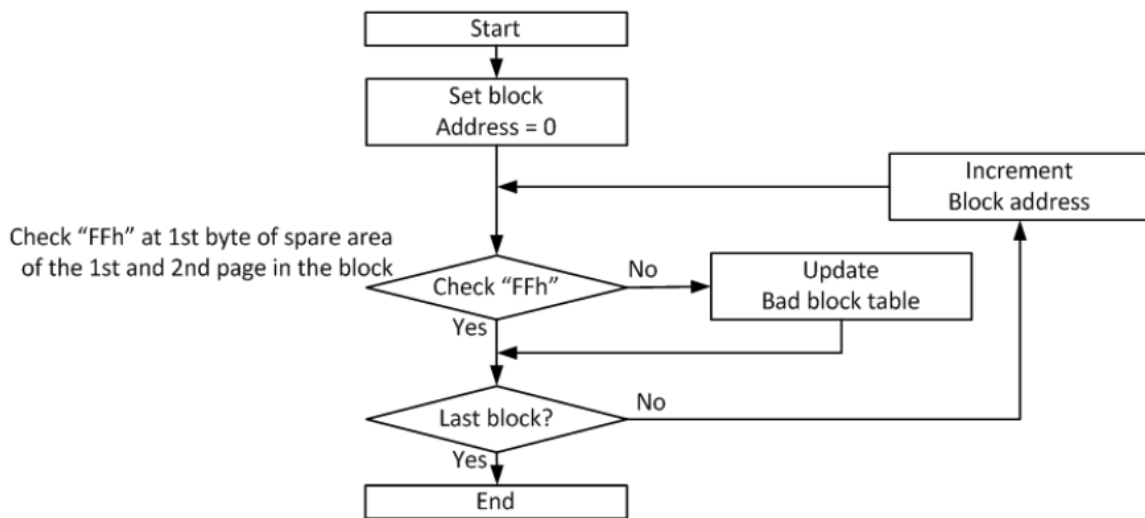

Parameter	Symbol	Min	Max	Unit
Valid block number	Nvb	1004	1024	blocks

Initial Invalid Blocks

Initial invalid blocks are defined as blocks that contain one or more invalid bits when shipped from factory.

Although the device contains initial invalid blocks, a valid block of the device is of the same quality and reliability as all valid blocks in the device with reference to AC and DC specifications. The H7A11G24B9CN has internal circuits to isolate each block from other blocks and therefore, the invalid blocks will not affect the performance of the entire device.

Before the device is shipped from the factory, it will be erased and invalid blocks are marked. All initial invalid blocks are marked with non-FFh at the first byte of spare area on the 1st or 2nd page. The initial invalid block information cannot be recovered if inadvertently erased. Therefore, software should be created to initially check for invalid blocks by reading the marked locations before performing any program or erase operation, and create a table of initial invalid blocks as following flow chart.

flow chart of create initial invalid block table

Error in operation

Additional invalid blocks may develop in the device during its life cycle. Following the procedures herein is required to guarantee reliable data in the device.

After each program and erase operation, check the status read to determine if the operation failed. In case of failure, a block replacement should be done with a bad-block management algorithm. The system has to use a minimum 1-bit ECC per 528 bytes of data to ensure data recovery.

Operation	Detection and recommended procedure
Erase	Status read after erase → Block Replacement
Program	Status read after program → Block Replacement
Read	Verify ECC → ECC correction

Bad block Replacement

Note 1: An error happens in the nth page of block A during program or erase operation.

Note 2: Copy the data in block A to the same location of block B which is valid block.

Note 3: Copy the nth page data of block A in the buffer memory to the nth page of block B

Note 4: Creating or updating bad block table for preventing further program or erase to block A

Addressing in program operation

The pages within the block have to be programmed sequentially from LSB (least significant bit) page to the MSB (most significant bit) within the block. The LSB is defined as the start page to program, does not need to be page 0 in the block. Random page programming is prohibited.
