

## 2Gb (16Mx8Banksx16) DDR2 SDRAM

### Descriptions

The H2A302G1656C is a high speed Double Data Rate 2 (DDR2) Synchronous DRAM fabricated with ultra high performance CMOS process containing 2G bits which organized as 16Mbits x 8 banks by 16 bits. This synchronous device achieves high speed double-data-rate transfer rates of up to 1066 Mb/sec/pin (DDR2-1066) for general applications. The chip is designed to comply with the following key DDR2 SDRAM features: (1) posted CAS with additive latency, (2) write latency = read latency -1, (3) Off-Chip Driver (OCD) impedance adjustment and On Die Termination (4) normal and weak strength data output driver. All of the control and address inputs are synchronized with a pair of externally supplied differential clocks. Inputs are latched at the cross point of differential clocks (CK rising and /CK falling). All I/Os are synchronized with a pair of bidirectional strobes (DQS and /DQS) in a source synchronous fashion. The address bus is used to convey row, column and bank address information in a /RAS and /CAS multiplexing style.

### Features

- JEDEC Standard VDD/VDDQ = 1.8V±0.1V.
- All inputs and outputs are compatible with SSTL\_18 interface.
- Fullydifferential clock inputs (CK, /CK) operation.
- Eight Banks
- Posted CAS
- Bust length: 4 and 8.
- Programmable CAS Latency (CL): 3, 4, 5, 6, 7
- Write Latency (WL) =Read Latency (RL) -1.
- Read Latency (RL) = Programmable Additive Latency (AL) + CAS Latency (CL)
- Bi-directional DifferentialData Strobe (DQS).
- Data inputs on DQS centers when write.
- Data outputs on DQS, /DQS edges when read.
- On chip DLL align DQ, DQS and /DQS transition with CK transition.
- DM mask write data-in at the both rising and falling edges of the data strobe.
- Sequential & Interleaved Burst type available.
- Off-Chip Driver (OCD) Impedance Adjustment
- On Die Termination (ODT)
- Auto Refresh and Self Refresh
- RoHS Compliance
- Partial Array Self-Refresh (PASR)
- High Temperature Self-Refresh rate enable

**Ordering Information**

Part No	Organization	Max. Freq	Package	Grade
H2A302G1656CAAFC	128M X 16	DDR2-667MHz 5-5-5	84Ball BGA, 9x12.5mm	Commercial
H2A302G1656CBAFC	128M X 16	DDR2-800MHz 6-6-6	84Ball BGA, 9x12.5mm	Commercial
H2A302G1656CCAFC	128M X 16	DDR2-1066MHz 7-7-7	84Ball BGA, 9x12.5mm	Commercial

Note: Speed (tck\*) is in order of CL-T<sub>RCD</sub>-T<sub>RP</sub>

## 84-Ball FBGA – x16 Ball Descriptions

Pin	Symbol	Description
M8,M3,M7,N2, N8,N3,N7,P2, P8,P3,M2,P7, R2,R8	A0–A13	<b>( Address)</b> Provide the row address for active commands, and the column address and Auto-precharge bit for Read/Write commands to select one location out of the memory array in the respective bank. Row address: A0–A13. Column address: A0–A9. (A10 is used for Auto-precharge)
L1,L2,L3	BA0–BA1	<b>( Bank Select)</b> BA0–BA1 define to which bank an ACTIVE, READ, WRITE or PRECHARGE command is being applied.
G8,G2,H7,H3, H1,H9,F1,F9, C8,C2,D7,D3, D1,D9,B1,B9	DQ0–DQ15	<b>( Data Input / Output)</b> Bi-directional data bus.
K9	ODT	<b>( On Die Termination Control)</b> ODT (registered HIGH) enables termination resistance internal to the DDR2 SDRAM.
F7,E8	LDQS, /LDQS	<b>( LOW Data Strobe)</b> Data Strobe for Lower Byte: Output with read data, input with write data for source synchronous operation. Edge-aligned with read data, centraligned with write data. LDQS corresponds to the data on DQ0–DQ7. /LDQS is only used when differential data strobe mode is enabled via the control bit at EMR (1)[A10 EMRS command].
B7,A8	UDQS, /UDQS	<b>( UP Data Strobe)</b> Data Strobe for Upper Byte: Output with read data, input with write data for source synchronous operation. Edge-aligned with read data, centraligned with write data. UDQS corresponds to the data on DQ8–DQ15. /UDQS is only used when differential data strobe mode is enabled via the control bit at EMR (1)[A10 EMRS command].
L8	/CS	<b>( Chip Select)</b> All commands are masked when /CS is registered HIGH. /CS provides for external rank selection on systems with multiple ranks. CS is considered part of the command code.
K7,L7,K3	/RAS , /CAS , /WE	<b>( Command Inputs)</b> /RAS , /CAS and /WE (along with /CS ) define the command being entered.

B3,F3	UDM, LDM	<p><b>( Input Data Mask)</b> DM is an input mask signal for write data. Input data is masked when DM is sampled high coincident with that input data during a Write access. DM is sampled on both edges of DQS. Although DM pins are input only, the DM loading matches the DQ and DQS loading.</p>
J8,K8	CK, /CK	<p><b>( Differential Clock Inputs)</b> CLK and /CLK are differential clock inputs. All address and control input signals are sampled on the crossing of the positive edge of CLK and negative edge of /CLK . Output (read) data is referenced to the crossings of CLK and /CLK (both directions of crossing).</p>
K2	CKE	<p><b>( Clock Enable)</b> CKE (registered HIGH) activates and CKE (registered LOW) deactivates clocking circuitry on the DDR2 SDRAM.</p>
J2	VREF	<p><b>( Reference Voltage)</b> VREF is reference voltage for inputs</p>
A1,E1,J9,M9,R1	VDD	<p><b>( Power Supply)</b> Power Supply: 1.8V <math>\pm</math> 0.1V.</p>
A3,E3,J3,N1,P9	VSS	<p><b>( Ground)</b> Ground.</p>
A9,C1,C3,C7, C9,E9,G1,G3, G7,G9	VDDQ	<p><b>( DQ Power Supply)</b> DQ Power Supply: 1.8V <math>\pm</math> 0.1V.</p>
A7,B2,B8,D2, D8,E7,F2,F8, H2,H8	VSSQ	<p><b>( DQ Ground)</b> DQ Ground. Isolated on the device for improved noise immunity</p>
A2,E2,L1,R3, R7	NC	<p><b>( No Connection)</b> No connection</p>
J7	VSSDL	<p><b>( DLL Ground)</b> DLL Ground</p>
J1	VDDL	<p><b>( DLL Power Supply)</b> DLL Power Supply: 1.8V <math>\pm</math> 0.1V.</p>

### Absolute Maximum Ratings

Symbol	Item	Rating		Units
$V_{IN}, V_{OUT}$	Input, Output Voltage	-0.5 ~ +2.3		V
$V_{DD}$	Power Supply Voltage	-1.0 ~ +2.3		V
$V_{DDQ}$	Power Supply Voltage	-0.5 ~ +2.3		V
VDDL	DLL Power Supply Voltage	-0.5 ~ +2.3		V
$T_{OP}$	Operating Temperature Range	Commercial	0 ~ +85	°C
$T_{STG}$	Storage Temperature Range	-55 ~ +100		°C
$P_D$	Power Dissipation	1		W

**Note:** Caution Exposing the device to stress above those listed in Absolute Maximum Ratings could cause permanent damage. The device is not meant to be operated under conditions outside the limits described in the operational section of this specification.

### Recommended DC Operating Conditions

Symbol	Parameter	Min.	Typ.	Max.	Units
$V_{DD}$	Power Supply Voltage	1.7	1.8	1.9	V
VDDL	Power Supply for DLL Voltage	1.7	1.8	1.9	V
$V_{DDQ}$	Power Supply for I/O Voltage	1.7	1.8	1.9	V
$V_{REF}$	I/O Reference Voltage	$0.49 \times V_{DDQ}$	$0.5 \times V_{DDQ}$	$0.51 \times V_{DDQ}$	V
$V_{TT}$	I/O Termination Voltage	$V_{REF} - 0.04$	$V_{REF}$	$V_{REF} + 0.04$	V
$V_{ID}$	DC Differential Input Voltage	0.25	-	$V_{DDQ} + 0.6$	V
$V_{IH}$	Input Logic High Voltage	$V_{REF} + 0.125$	-	$V_{DDQ} + 0.3$	V
$V_{IL}$	Input Logic Low Voltage	-0.3	-	$V_{REF} - 0.125$	V

### Input / Output Capacitance

Symbol	Parameters	Min.	Max.	Unit
$C_{CK}$	Input Capacitance , CLK and /CLK	1.0	2.0	pF
$CD_{CK}$	Input Capacitance delta , CLK and /CLK	-	0.25	pF
$C_I$	Input Capacitance, all other input-only pins	1.0	1.75	pF
$CD_I$	Input Capacitance delta, all other input-only pins	-	0.25	pF
$C_{IO}$	Input/output Capacitance, DQ, LDM, UDM, LDQS, /LDQS , UDQS, /UDQS	2.5	4.0	pF
$CD_{IO}$	Input/output Capacitance delta, DQ, LDM, UDM, LDQS, /LDQS , UDQS, /UDQS	-	0.5	pF

## Recommended DC Operating Conditions

Symbol	Parameter & Test Conditions	1066MHz	800MHz	667MHz	Units	NOTES
		Max				
IDD0	<b>Operating Current - One Bank Active-Precharge</b> tCK = tCK(IDD), tRC = tRC(IDD), tRAS = tRASmin(IDD); CKE is HIGH, /CS is HIGH between valid commands; Address and control inputs are SWITCHING; Databus inputs are SWITCHING.	100	90	85	mA	1,2,3, 4,5,6
IDD1	<b>Operating Current - One Bank Active-Read-Precharge</b> IOUT = 0 mA; BL = 4, CL = CL(IDD), AL = 0; tCK = tCK(IDD), tRC = tRC(IDD), tRAS = tRASmin(IDD), tRCD = tRCD(IDD); CKE is HIGH, /CS is HIGH between valid commands; Address and control inputs are SWITCHING; Data bus inputs are SWITCHING.	110	105	100	mA	1,2,3, 4,5,6
IDD2P	<b>Precharge Power-Down Current</b> All banks idle; tCK = tCK(IDD); CKE is LOW; Other control and address inputs are STABLE; Data Bus inputs are FLOATING. (TCASE ≤ 85°C)	12	12	12	mA	1,2,3,4, 5,6,7
IDD2N	<b>Precharge Standby Current</b> All banks idle; tCK = tCK(IDD); CKE is HIGH, /CS is HIGH; Other control and address inputs are SWITCHING; Data bus inputs are SWITCHING.	55	50	45	mA	1,2,3, 4,5,6
IDD2Q	<b>Precharge Quiet Standby Current</b> All banks idle; tCK = tCK(IDD); CKE is HIGH, /CS is HIGH; Other control and address inputs are STABLE; Data bus inputs are FLOATING.	50	45	40	mA	1,2,3, 4,5,6

IDD3PF	<b>Active Power Down Current</b> All banks open; tCK = tCK(IDD); CKE is LOW; Other control and address input	Fast PDN Exit MRS(12) = 0	25	25	25	mA	1,2,3, 4,5,6
IDD3PS	are STABLE; Data bus inputs are FLOATING. (TCASE≤85°C)	Slow PDN Exit MRS(12) = 1	14	14	14	mA	1,2,3,4, 5,6,7
IDD3N	<b>Active Standby Current</b> All banks open; tCK = tCK(IDD); tRAS = tRASmax(IDD), tRP = tRP(IDD); CKE is HIGH, /CS is HIGH between valid commands; Other control and address inputs are SWITCHING; Data bus inputs are SWITCHING.		60	50	45	mA	1,2,3, 4,5,6
IDD4R	<b>Operating Burst Read Current</b> All banks open, Continuous burst reads, IOOUT = 0 mA; BL = 4, CL = CL(IDD), AL = 0; tCK = tCK(IDD); tRAS = tRASmax(IDD), tRP = tRP(IDD); CKE is HIGH, /CS is HIGH between valid commands; Address inputs are SWITCHING; Data Bus inputs are SWITCHING.		210	190	170	mA	1,2,3, 4,5,6
IDD4W	<b>Operating Burst Write Current</b> All banks open, Continuous burst writes; BL = 4, CL = CL(IDD), AL = 0; tCK = tCK(IDD); tRAS = tRASmax(IDD), tRP = tRP(IDD); CKE is HIGH, /CS is HIGH between valid commands; Address inputs are SWITCHING; Data Bus inputs are SWITCHING.		210	190	170	mA	1,2,3, 4,5,6
IDD5B	<b>Burst Refresh Current</b> tCK = tCK(IDD); Refresh command every tRFC(IDD) interval; CKE is HIGH, /CS is HIGH between valid commands; Other control and address inputs are SWITCHING; Data bus inputs are SWITCHING.		175	170	165	mA	1,2,3, 4,5,6

IDD6	<b>Self Refresh Current</b> CKE $\leq 0.2$ V, external clock off, CLK and /CLK at 0 V; Other control and address inputs are FLOATING; Data bus inputs are FLOATING. (TCASE $\leq 85^{\circ}\text{C}$ )	12	12	12	mA	1,2,3,4,5,6,7
IDD7	<b>Operating Bank Interleave Read Current</b> All bank interleaving reads, IOU T = 0mA; BL = 4, CL = CL(IDD), AL = tRCD(IDD) - 1 x tCK(IDD); tCK = tCK(IDD), tRC = tRC(IDD), tRRD = tRRD(IDD), tFAW = tFAW(IDD), tRCD = tRCD(IDD); CKE is HIGH, /CS is HIGH between valid commands; Address bus inputs are STABLE during deselects; Data Bus inputs are SWITCHING.	290	280	250	mA	1,2,3,4,5,6

**Note 1:** VDD = 1.8 V  $\pm$  0.1V; VDDQ = 1.8 V  $\pm$  0.1V.

**Note 2:** IDD specifications are tested after the device is properly initialized.

**Note 3:** Input slew rate is specified by AC Parametric Test Condition.

**Note 4:** IDD parameters are specified with ODT disabled.

**Note 5:** Data Bus consists of DQ, LDM, UDM, LDQS, /LDQS, UDQS and /UDQS

**Note 6:** Definitions for IDD

LOW =  $V_{in} \leq V_{IL} (ac)$  (max)

HIGH =  $V_{in} \geq V_{IH} (ac)$  (min)

STABLE = inputs stable at a HIGH or LOW level

FLOATING = inputs at  $V_{REF} = V_{DDQ}/2$

SWITCHING = inputs changing between HIGH and LOW every other clock cycle (once per two clocks) for address and control signals, and inputs changing between HIGH and LOW every other data transfer (once per clock) for DQ signals not including masks or strobes.

**Note 7:** The following IDD values must be derated (IDD limits increase), when TCASE  $\geq 85^{\circ}\text{C}$  IDD2P must be derated by 20%; IDD3P(slow) must be derated by 30% and IDD6 must be derated by 80%. (IDD6 will increase by this amount if TCASE  $< 85^{\circ}\text{C}$  and the 2X refresh option is still enabled)

## Block Diagram

## Output Characteristics

Parameter	Min.	Typ.	Max.	Units
Output Impedance	-	-	-	$\Omega$
Pull-up / Pull-down mismatch	0	-	4	$\Omega$
Output Slew Rate	1.5	-	5.0	V/ns

**Note 1:** Absolute specifications:  $0^{\circ}\text{C} \leq \text{TC} \leq +85^{\circ}\text{C}$ ;  $\text{VDDQ} = 1.8\text{V} \pm 0.1\text{V}$ ,  $\text{VDD} = 1.8\text{V} \pm 0.1\text{V}$ .

**Note 2:** Impedance measurement conditions for output source DC current:  $\text{VDDQ} = 1.7\text{V}$ ;  $\text{VOUT} = 1420\text{mV}$ ;  $(\text{VOUT} - \text{VDDQ})/\text{IOH}$  must be less than  $23.4 \Omega$  for values of  $\text{VOUT}$  between  $\text{VDDQ}$  and  $\text{VDDQ} - 280\text{mV}$ . The impedance measurement condition for output sink DC current:  $\text{VDDQ} = 1.7\text{V}$ ;  $\text{VOUT} = 280\text{mV}$ ;  $\text{VOUT}/\text{IOL}$  must be less than  $23.4 \Omega$  for values of  $\text{VOUT}$  between  $0\text{V}$  and  $280\text{mV}$ .

**Note 3:** Mismatch is an absolute value between pull-up and pull-down; both are measured at the same temperature and voltage.

**Note 4:** Output slew rate for falling and rising edges is measured between  $\text{VTT} - 250\text{mV}$  and  $\text{VTT} + 250\text{mV}$  for single-ended signals. For differential signals (DQS, DQS#), output slew rate is measured between  $\text{DQS} - \text{DQS\#} = -500\text{mV}$  and  $\text{DQS\#} - \text{DQS} = 500\text{mV}$ . Output slew rate is guaranteed by design but is not necessarily tested on each device.

**Note 5:** The absolute value of the slew rate as measured from  $\text{VIL}(\text{DC})_{\text{max}}$  to  $\text{VIH}(\text{DC})_{\text{min}}$  is equal to or greater than the slew rate as measured from  $\text{VIL}(\text{AC})_{\text{max}}$  to  $\text{VIH}(\text{AC})_{\text{min}}$ . This is guaranteed by design and characterization.

**Note 6:** IT and AT devices require an additional  $0.4 \text{ V/ns}$  in the MAX limit when  $\text{TC}$  is between  $40^{\circ}\text{C}$  and  $0^{\circ}\text{C}$ .

## AC Operating Test Conditions

Symbol	Parameter	Value	Units
VSWING (max.)	Input Signal Maximum Peak to Peak Swing	1.0	V
SLEW	Input Signal Minimum Slew Rate	1.0	V/ns
VREF	Input Reference Level	$0.5 \cdot \text{VDDQ}$	V

**Note 1:** Input waveform timing is referenced to the input signal crossing through the  $\text{VIH}/\text{IL}(\text{ac})$  level applied to the device under test.

**Note 2:** The input signal minimum slew rate is to be maintained over the range from  $\text{VREF}$  to  $\text{VIH}(\text{ac})_{\text{min}}$  for rising edges and the range from  $\text{VREF}$  to  $\text{VIL}(\text{ac})_{\text{max}}$  for falling edges as shown in the below figure.

**Note 3:** AC timings are referenced with input waveforms switching from  $\text{VIL}(\text{ac})$  to  $\text{VIH}(\text{ac})$  on the positive transitions and  $\text{VIH}(\text{ac})$  to  $\text{VIL}(\text{ac})$  on the negative transitions.

## AC Operating Test Conditions

Symbol	Parameter	Min.	Max.	Units
$\text{V}_{\text{ID}}$	AC Differential Input Voltage	0.5	$\text{VDDQ} + 0.6$	V
$\text{V}_{\text{IX}}$	AC Differential Cross Point Input Voltage	$0.5 \cdot \text{VDDQ} - 0.175$	$0.5 \cdot \text{VDDQ} + 0.175$	V
$\text{V}_{\text{OX}}$	AC Differential Cross Point Output Voltage	$0.5 \cdot \text{VDDQ} - 0.125$	$0.5 \cdot \text{VDDQ} + 0.125$	V
$\text{V}_{\text{IH}}$	Input Logic High Voltage	$\text{VREF} + 0.20$	$\text{VDDQ}$	V
$\text{V}_{\text{IL}}$	Input Logic High Voltage	-0.30	$\text{VREF} - 0.20$	V

**Note 1:** All voltages are referenced to VSS.

**Note 2:** Tests for AC timing, IDD, and electrical AC and DC characteristics may be conducted at nominal reference/supply voltage levels, but the related specifications and device operation are guaranteed for the full voltage range specified. ODT is disabled for all measurements that are not ODT-specific.

**Note 3:** AC timing reference load:

**Note 4:** This is a minimum requirement. Minimum read to precharge timing is  $AL + BL / 2$  provided that the tRTP and tRAS(min) have been satisfied.

**Note 5:** If refresh timing is violated, data corruption may occur and the data must be re-written with valid data before a valid READ can be executed.

**Note 6:** This is an optional feature. For detailed information, please refer to “**Operating Temperature Condition**” section 10.2 in this data sheet.

**Note 7:** tCKE min of 3 clocks means CKE must be registered on three consecutive positive clock edges. CKE must remain at the valid input level the entire time it takes to achieve the 3 clocks of registration. Thus, after any CKE transition, CKE may not transition from its valid level during the time period of  $tIS + 2 \times tCK + tIH$ .

**Note 8:** A minimum of two clocks ( $2 \times nCK$ ) is required irrespective of operating frequency.

**Note 9:** tWTR is at least two clocks ( $2 \times nCK$ ) independent of operation frequency.

**Note 10:** There are two sets of values listed for Command/Address input setup time: tIS(base) and tIS(ref). The tIS(ref) value (for reference only) is equivalent to the baseline value of tIS(base) at VREF when the slew rate is 1.0 V/nS. The baseline value tIS(base) is the JEDEC defined value, referenced from the input signal crossing at the VIH(ac) level for a rising signal and VIL(ac) for a falling signal applied to the device under test. See Figure 17. If the Command/Address slew rate is not equal to 1.0 V/nS, then the baseline values must be derated by adding the values from table of tIS/tIH derating values for DDR2-667, DDR2-800 and DDR2-1066

Differential input waveform timing – tIS and tIH

**Note 11:** There are two sets of values listed for Command/Address input hold time:  $t_{IH}(\text{base})$  and  $t_{IH}(\text{ref})$ . The  $t_{IH}(\text{ref})$  value (for reference only) is equivalent to the baseline value of  $t_{IH}(\text{base})$  at  $V_{REF}$  when the slew rate is 1.0 V/nS. The baseline value  $t_{IH}(\text{base})$  is the JEDEC defined value, referenced from the input signal crossing at the  $V_{IL(\text{dc})}$  level for a rising signal and  $V_{IH(\text{dc})}$  for a falling signal applied to the device under test. See Figure 17. If the Command/Address slew rate is not equal to 1.0 V/nS, then the baseline values must be derated by adding the values from table tIS/tIH derating values for DDR2-667, DDR2-800 and DDR2-1066

**Note 12:** The maximum limit for the  $t_{WPST}$  parameter is not a device limit. The device operates with a greater value for this parameter, but system performance (bus turnaround) will degrade accordingly.

**Note 13:**  $t_{DQSQ}$ : Consists of data pin skew and output pattern effects, and p-channel to n-channel variation of the output drivers as well as output Slew Rate mismatch between DQS / DQS and associated DQ in any given cycle.

**Note 14:**  $t_{RPST}$  end point and  $t_{RPRE}$  begin point are not referenced to a specific voltage level but specify when the device output is no longer driving ( $t_{RPST}$ ), or begins driving ( $t_{RPRE}$ ). Figure 18 shows a method to calculate these points when the device is no longer driving ( $t_{RPST}$ ), or begins driving ( $t_{RPRE}$ ) by measuring the signal at two different voltages. The actual voltage measurement points are not critical as long as the calculation is consistent.

**Note 15:**  $t_{HZ}$  and  $t_{LZ}$  transitions occur in the same access time as valid data transitions. These parameters are referenced to a specific voltage level which specifies when the device output is no longer driving ( $t_{HZ}$ ), or begins driving ( $t_{LZ}$ ). Figure 18 shows a method to calculate the point when device is no longer driving ( $t_{HZ}$ ), or begins driving ( $t_{LZ}$ ) by measuring the signal at two different voltages. The actual voltage measurement points are not critical as long as the calculation is consistent.  $t_{LZ}(\text{DQ})$  refers to  $t_{LZ}$  of the DQ's and  $t_{LZ}(\text{DQS})$  refers to  $t_{LZ}$  of the (UDQS, LDQS, /UDQS and /LDQS) each treated as single-ended signal.

Method for calculating transitions and endpoints

**Note 16:** Input waveform timing tDS with differential data strobe enabled MR[bit10]=0. There are two sets of values listed for DQ and DM input setup time: tDS(base) and tDS(ref). The tDS(ref) value (for reference only) is equivalent to the baseline value tDS(base) at VREF when the slew rate is 2.0 V/nS, differentially. The baseline value tDS(base) is the JEDEC defined value, referenced from the input signal crossing at the VIH(ac) level to the differential data strobe crosspoint for a rising signal, and from the input signal crossing at the VIL(ac) level to the differential data strobe crosspoint for a falling signal applied to the device under test. DQS, /DQS signals must be monotonic between VIL(dc)max and VIH(dc)min. If the differential DQS slew rate is not equal to 2.0 V/nS, then the baseline values must be derated by adding the values from table of DDR2-667, DDR2-800 and DDR2-1066 tDS/tDH derating with differential data strobe

**Note 17:** Input waveform timing tDH with differential data strobe enabled MR[bit10]=0. There are two sets of values listed for DQ and DM input hold time: tDH(base) and tDH(ref). The tDH(ref) value (for reference only) is equivalent to the baseline value tDH(base) at VREF when the slew rate is 2.0 V/nS, differentially. The baseline value tDH(base) is the JEDEC defined value, referenced from the differential data strobe crosspoint to the input signal crossing at the VIH(dc) level for a falling signal and from the differential data strobe crosspoint to the input signal crossing at the VIL(dc) level for a rising signal applied to the device under test. DQS, /DQS signals must be monotonic between VIL(dc)max and VIH(dc)min. If the differential DQS slew rate is not equal to 2.0 V/nS, then the baseline values must be derated by adding the values from table of DDR2-667, DDR2-800 and DDR2-1066 tDS/tDH derating with differential data strobe

Differential input waveform timing – tDS and tDH

**Note 18:** User can choose which active power down exit timing to use via MRS (bit 12). tXARD is expected to be used for fast active power down exit timing. tXARDS is expected to be used for slow active power down exit timing.

**Note 19:** AL = Additive Latency.

**Note 20:** ODT turn on time min is when the device leaves high impedance and ODT resistance begins to turn on. ODT turn on time max is when the ODT resistance is fully on. Both are measure from tAOND, which is interpreted differently per speed bin. For DDR2-667/800/1066, tAOND is 2 clock cycles after the clock edge that registered a first ODT HIGH counting the actual input clock edges.

**Note 21:** ODT turn off time min is when the device starts to turn off ODT resistance. ODT turn off time max is when the bus is in high impedance. Both are measured from tAOFD, which is interpreted as  $0.5 \times tCK(\text{avg})$  [nS] after the second trailing clock edge counting from the clock edge that registered a first ODT LOW and by counting the actual input clock edges. For DDR2-667/800: If  $tCK(\text{avg}) = 3$  nS is assumed, tAOFD is 1.5 nS ( $= 0.5 \times 3$  nS) after the second trailing clock edge counting from the clock edge that registered a first ODT LOW and by counting the actual input clock edges. For DDR2-1066: tAOFD is 0.9375 [nS] ( $= 0.5 \times 1.875$  [nS]) after the second trailing clock edge counting from the clock edge that registered a first ODT LOW and by counting the actual input clock edges.

**Note 22:** The clock frequency is allowed to change during Self Refresh mode or precharge power-down mode. In case of clock frequency change during precharge power-down, a specific procedure is required as described in section 8.10.

**Note 23:** For these parameters, the DDR2 SDRAM device is characterized and verified to support  $tnPARAM = RU\{tPARAM / tCK(\text{avg})\}$ , which is in clock cycles, assuming all input clock jitter specifications are satisfied.

Examples:

The device will support  $tnRP = RU\{tRP / tCK(\text{avg})\}$ , which is in clock cycles, if all input clock jitter specifications are met. This means: For DDR2-667 5-5-5, of which  $tRP = 15$ nS, the device will support  $tnRP = RU\{tRP / tCK(\text{avg})\} = 5$ , i.e. as long as the input clock jitter specifications are met, Precharge command at  $T_m$  and Active command at  $T_m+5$  is valid even if  $(T_m+5 - T_m)$  is less than 15nS due to input clock jitter. For DDR2-1066 7-7-7, of which  $tRP = 13.125$  nS, the device will support  $tnRP = RU\{tRP / tCK(\text{avg})\} = 7$ , i.e. as long as the input clock jitter specifications are

met, Precharge command at  $T_m$  and Active command at  $T_m+7$  is valid even if  $(T_m+7 - T_m)$  is less than 13.125 nS due to input clock jitter.

**Note 24:**  $tDAL [nCK] = WR [nCK] + tnRP [nCK] = WR + RU \{tRP [pS] / tCK(\text{avg}) [pS]\}$ , where WR is the value programmed in the mode register set and RU stands for round up.

Example:

For DDR2-1066 7-7-7 at  $tCK(\text{avg}) = 1.875$  nS with WR programmed to 8 nCK,  $tDAL = 8 + RU \{13.125 \text{ nS} / 1.875 \text{ nS}\} [nCK] = 8 + 7 [nCK] = 15 [nCK]$ .

**Note 25:** New units, 'tCK(avg)' and 'nCK', are introduced in DDR2-667, DDR2-800 and DDR2-1066.

Unit 'tCK(avg)' represents the actual tCK(avg) of the input clock under operation. Unit 'nCK' represents one clock cycle of the input clock, counting the actual clock edges.

Examples:

For DDR2-667/800:  $tXP = 2 [nCK]$  means; if Power Down exit is registered at  $T_m$ , an Active command may be registered at  $T_m+2$ , even if  $(T_m+2 - T_m)$  is  $2 \times tCK(\text{avg}) + tERR(2\text{per}),\text{min}$ . For DDR2-1066:  $tXP = 3 [nCK]$  means; if Power Down exit is registered at  $T_m$ , an Active command may be registered at  $T_m+3$ , even if  $(T_m+3 - T_m)$  is  $3 \times tCK(\text{avg}) + tERR(3\text{per}),\text{min}$ .

**Note 26:** These parameters are measured from a command/address signal (CKE, /CS, /RAS, /CAS, /WE, ODT, BA0, A0, A1, etc.) transition edge to its respective clock signal (CLK/ /CLK) crossing. The spec values are not affected by the amount of clock jitter applied (i.e. tJIT(per), tJIT(cc), etc.), as the setup and hold are relative to the clock signal crossing that latches the command/address. That is, these parameters should be met whether clock jitter is present or not.

**Note 27:** If tDS or tDH is violated, data corruption may occur and the data must be re-written with valid data before a valid READ can be executed.

**Note 28:** These parameters are measured from a data strobe signal ((L/U)DQS/ /DQS) crossing to its respective clock signal (CLK/ /CLK) crossing. The spec values are not affected by the amount of clock jitter applied (i.e. tJIT(per), tJIT(cc), etc.), as these are relative to the clock signal crossing. That is, these parameters should be met whether clock jitter is present or not.

**Note 29:** These parameters are measured from a data signal ((L/U)DM, (L/U)DQ0, (L/U)DQ1, etc.) transition edge to its respective data strobe signal ((L/U)DQS/ /DQS) crossing.

**Note 30:** Input clock jitter spec parameter. These parameters and the ones in the table below are referred to as 'input clock jitter spec parameters'. The jitter specified is a random jitter meeting a Gaussian distribution.

### Input clock-Jitter specifications parameters for DDR2-667, DDR2-800 and DDR2-1066

PARAMETER	SYMBOL	DDR2-667		DDR2-800		DDR2-1066		UNIT
		Min.	Max.	Min.	Max.	Min.	Max.	
Clock period jitter	Duty cycle jitter	-125	125	-100	100	-90	90	ps
Clock period jitter during DLL locking period	tJIT(per,lck)	-100	100	-80	80	-80	80	ps
Cycle to cycle clock period	tJIT(cc)	-250	250	-200	200	-180	180	ps
Cycle to cycle clock period jitter during DLL locking period	tJIT(cc,lck)	-200	200	-160	160	-160	160	ps
Cumulative error across 2 cycles	tERR(2per)	-175	175	-150	150	-132	132	ps
Cumulative error across 3 cycles	tERR(3per)	-225	225	-175	175	-157	157	ps
Cumulative error across 4 cycles	tERR(4per)	-250	250	-200	200	-157	157	ps
Cumulative error across 5 cycles	tERR(5per)	-250	250	-200	200	-188	188	ps
Cumulative error across n cycles, n = 6 ... 10, inclusive	tERR(6-10per)	-350	350	-300	300	-250	250	ps
Cumulative error across n cycles, n = 11 ... 50, inclusive	tERR(11-50per)	-450	450	-450	450	-425	425	ps
Duty cycle jitter	tJIT(duty)	-125	125	-100	100	-75	75	ps

**Note 31:** These parameters are specified per their average values, however it is understood that the following relationship between the average timing and the absolute instantaneous timing holds at all times. (Min and max of SPEC values are to be used for calculations in the table below.)

Parameter	SYMBOL	Min.	Max.	Units
Absolute clock period	tCK(abs)	tCK(avg),min+tJIT(per),min	tCK(avg),max + tJIT(per),max	ps
Absolute clock HIGH pulse width	tCH(abs)	tCH(avg),min x tCK(avg),min + tJIT(duty),min	tCH(avg),max x tCK(avg),max + tJIT(duty),max	ps
Absolute clock LOW pulse width	tCL(abs)	tCL(avg),min x tCK(avg),min + tJIT(duty),min	tCL(avg),max x tCK(avg),max + tJIT(duty),max	ps

**Note 32:** tHP is the minimum of the absolute half period of the actual input clock. tHP is an input parameter but not an input specification parameter. It is used in conjunction with tQHS to derive the DRAM output timing tQH. The value to be used for tQH calculation is determined by the following equation;  $tHP = \text{Min} ( tCH(\text{abs}), tCL(\text{abs}) )$ , where, tCH(abs) is the minimum of the actual instantaneous clock HIGH time; tCL(abs) is the minimum of the actual instantaneous clock LOW time;

**Note 33:** tQHS accounts for:

- 1) The pulse duration distortion of on-chip clock circuits, which represents how well the actual tHP at the input is transferred to the output; and
- 2) The worst case push-out of DQS on one transition followed by the worst case pull-in of DQ on the next transition, both of which are independent of each other, due to data pin skew, output pattern effects, and p-channel to nchannel variation of the output drivers

**Note 34:**  $tQH = tHP - tQHS$ , where:

tHP is the minimum of the absolute half period of the actual input clock; and tQHS is the specification value under the max column. {The less half-pulse width distortion present, the larger the tQH value is; and the larger the valid data eye will be.} Examples:

- 1) If the system provides tHP of 1315 pS into a DDR2-667 SDRAM, the DRAM provides tQH of 975 pS minimum.
- 2) If the system provides tHP of 1420 pS into a DDR2-667 SDRAM, the DRAM provides tQH of 1080 pS minimum.
- 3) If the system provides tHP of 825 pS into a DDR2-1066 SDRAM, the DRAM provides tQH of 575 pS minimum.
- 4) If the system provides tHP of 900 pS into a DDR2-1066 SDRAM, the DRAM provides tQH of 650 pS minimum.

**Note 35:** When the device is operated with input clock jitter, this parameter needs to be derated by the actual tERR(6-10per) of the input clock. (output deratings are relative to the SDRAM input clock.) Examples:

- 1) If the measured jitter into a DDR2-667 SDRAM has tERR(6-10per),min = - 272 pS and tERR(6-10per),max = + 293 pS, then  $tDQSCK,\text{min}(\text{derated}) = tDQSCK,\text{min} - tERR(6-10per),\text{max} = - 400 \text{ pS} - 293 \text{ pS} = - 693 \text{ pS}$  and  $tDQSCK,\text{max}(\text{derated}) = tDQSCK,\text{max} - tERR(6-10per),\text{min} = 400 \text{ pS} + 272 \text{ pS} = + 672 \text{ pS}$ . Similarly, tLZ(DQ) for DDR2-667 derates to  $tLZ(DQ),\text{min}(\text{derated}) = - 900 \text{ pS} - 293 \text{ pS} = - 1193 \text{ pS}$  and  $tLZ(DQ),\text{max}(\text{derated}) = 450 \text{ pS} + 272 \text{ pS} = + 722 \text{ pS}$ . (Caution on the min/max usage!)
- 2) If the measured jitter into a DDR2-1066 SDRAM has tERR(6-10per),min = - 202 pS and tERR(6-10per),max = + 223 pS, then  $tDQSCK,\text{min}(\text{derated}) = tDQSCK,\text{min} - tERR(6-10per),\text{max} = - 300 \text{ pS} - 223 \text{ pS} = - 523 \text{ pS}$  and  $tDQSCK,\text{max}(\text{derated}) = tDQSCK,\text{max} - tERR(6-10per),\text{min} = 300 \text{ pS} + 202 \text{ pS} = + 502 \text{ pS}$ . Similarly, tLZ(DQ) for DDR2-1066 derates to  $tLZ(DQ),\text{min}(\text{derated}) = - 700 \text{ pS} - 223 \text{ pS} = - 923 \text{ pS}$  and  $tLZ(DQ),\text{max}(\text{derated}) = 350 \text{ pS} + 202 \text{ pS} = + 552 \text{ pS}$ . (Caution on the min/max usage!)

- Note 36:** When the device is operated with input clock jitter, this parameter needs to be derated by the actual tJIT(per) of the input clock. (output deratings are relative to the SDRAM input clock.) Examples:
- 1) If the measured jitter into a DDR2-667 SDRAM has tJIT(per),min = - 72 pS and tJIT(per),max = + 93 pS, then tRPRE,min(derated) = tRPRE,min + tJIT(per),min = 0.9 x tCK(avg) - 72 pS = + 2178 pS and tRPRE,max(derated) = tRPRE,max + tJIT(per),max = 1.1 x tCK(avg) + 93 pS = + 2843 pS. (Caution on the min/max usage!)
  - 2) If the measured jitter into a DDR2-1066 SDRAM has tJIT(per),min = - 72 pS and tJIT(per),max = + 63 pS, then tRPRE,min(derated) = tRPRE,min + tJIT(per),min = 0.9 x tCK(avg) - 72 pS = + 1615.5 pS and tRPRE,max(derated) = tRPRE,max + tJIT(per),max = 1.1 x tCK(avg) + 63 pS = + 2125.5 pS. (Caution on the min/max usage!)

- Note 37:** When the device is operated with input clock jitter, this parameter needs to be derated by the actual tJIT(duty) of the input clock. (output deratings are relative to the SDRAM input clock.) Examples:
- 1) If the measured jitter into a DDR2-800 SDRAM has tJIT(duty),min = - 72 pS and tJIT(duty),max = + 93 pS, then tRPST,min(derated) = tRPST,min + tJIT(duty),min = 0.4 x tCK(avg) - 72 pS = + 928 pS and tRPST,max(derated) = tRPST,max + tJIT(duty),max = 0.6 x tCK(avg) + 93 pS = + 1593 pS. (Caution on the min/max usage!)
  - 2) If the measured jitter into a DDR2-1066 SDRAM has tJIT(duty),min = - 72 pS and tJIT(duty),max = + 63 pS, then tRPST,min(derated) = tRPST,min + tJIT(duty),min = 0.4 x tCK(avg) - 72 pS = + 678 pS and tRPST,max(derated) = tRPST,max + tJIT(duty),max = 0.6 x tCK(avg) + 63 pS = + 1188 pS. (Caution on the min/max usage!)

- Note 38:** When the device is operated with input clock jitter, this parameter needs to be derated by { -tJIT(duty), max - tERR(6- 10per),max } and { - tJIT(duty),min - tERR(6-10per),min } of the actual input clock. (output deratings are relative to the SDRAM input clock.) Examples:
- 1) If the measured jitter into a DDR2-667 SDRAM has tERR(6-10per),min = - 272 pS, tERR(6-10per),max = + 293 pS, tJIT(duty),min = - 106 pS and tJIT(duty),max = + 94 pS, then tAOF,min(derated) = tAOF,min + { - tJIT(duty),max - tERR(6-10per),max } = - 450 pS + { - 94 pS - 293 pS } = - 837 pS and tAOF,max(derated) = tAOF,max + { - tJIT(duty),min - tERR(6-10per),min } = 1050 pS + { 106 pS + 272 pS } = + 1428 pS. (Caution on the min/max usage!)
  - 2) If the measured jitter into a DDR2-1066 SDRAM has tERR(6-10per),min = - 202 pS, tERR(6-10per),max = + 223 pS, tJIT(duty),min = - 66 pS and tJIT(duty),max = + 74 pS, then tAOF,min(derated) = tAOF,min + { - tJIT(duty),max - tERR(6-10per),max } = - 350 pS + { - 74 pS - 223 pS } = - 647 pS and tAOF,max(derated) = tAOF,max + { - tJIT(duty),min - tERR(6-10per),min } = 950 pS + { 66 pS + 202 pS } = + 1218 pS. (Caution on the min/max usage!)

- Note 39:** For tAOFD of DDR2-667/800/1066, the 1/2 clock of nCK in the 2.5 x nCK assumes a tCH(avg), average input clock HIGH pulse width of 0.5 relative to tCK(avg). tAOF,min and tAOF,max should each be derated by the same amount as the actual amount of tCH(avg) offset present at the DRAM input with respect to 0.5. Example:

If an input clock has a worst case tCH(avg) of 0.48, the tAOF,min should be derated by subtracting 0.02 x tCK(avg) from it, whereas if an input clock has a worst case tCH(avg) of 0.52, the tAOF,max should be derated by adding 0.02 x tCK(avg) to it. Therefore, we have; tAOF,min(derated) = tAC,min - [0.5 - Min(0.5, tCH(avg),min)] x tCK(avg) tAOF,max(derated) = tAC,max + 0.6 + [Max(0.5, tCH(avg),max) - 0.5] x tCK(avg)

or

tAOF,min(derated) = Min(tAC,min, tAC,min - [0.5 - tCH(avg),min] x tCK(avg)) tAOF,max(derated) = 0.6 + Max(tAC,max, tAC,max + [tCH(avg),max - 0.5] x tCK(avg)) where tCH(avg),min and tCH(avg),max are

the minimum and maximum of tCH(avg) actually measured at the DRAM input balls. Note that these deratings are in addition to the tAOF derating per input clock jitter, i.e. tJIT(duty) and tERR(6-10per). However tAC values used in the equations shown above are from the timing parameter table and are not derated. Thus the final derated values for tAOF are; tAOF,min(derated\_final) = tAOF,min(derated) + { - tJIT(duty),max - tERR(6-10per),max } tAOF,max(derated\_final) = tAOF,max(derated) + { - tJIT(duty),min - tERR(6-10per),min }

**Note 40:** Timings are specified with command/address input slew rate of 1.0 V/nS.

**Note 41:** Timings are specified with DQs and DM input slew rate of 1.0V/nS.

**Note 42:** Timings are specified with CLK/ /CLK differential slew rate of 2.0 V/nS. Timings are guaranteed for DQS signals with a differential slew rate of 2.0 V/nS in differential strobe mode.

**Note 43:** tIS and tIH (input setup and hold) derating.

**Note 44:** Data setup and hold time derating.

Command/ Address Slew Rate (V/nS)	Δ tIS and Δ tIH Derating Values for DDR2-667, DDR2-800 and DDR2-1066						Unit

0.1	-1000	-1125	-970	-1095	-940	-1065	ps

For all input signals the total tIS (setup time) and tIH (hold time) required is calculated by adding the data sheet tIS(base) and tIH(base) value to the ΔtIS and ΔtIH derating value respectively. Example: tIS (total setup time) = tIS(base) + ΔtIS.

Setup (tIS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VREF(dc) and the first crossing of VIH(ac)min. Setup (tIS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VREF(dc) and the first crossing of VIL(ac)max. If the actual

signal is always earlier than the nominal slew rate line between shaded 'VREF(dc) to AC region', use nominal slew rate for derating value. See Figure 1 Illustration of nominal slew rate for tIS. If the actual signal is later than the nominal slew rate line anywhere between shaded 'VREF(dc) to AC region', the slew rate of a tangent line to the actual signal from the AC level to DC level is used for derating value. See Figure 2 Illustration of tangent line for tIS.

Hold (tIH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL(dc)max and the first crossing of VREF(dc). Hold (tIH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(dc)min and the first crossing of VREF(dc). If the actual signal is always later than the nominal slew rate line between shaded 'DC to VREF(dc) region', use nominal slew rate for derating value. See Figure 3 Illustration of nominal slew rate for tIH. If the actual signal is earlier than the nominal slew rate line anywhere between shaded 'DC to VREF(dc) region', the slew rate of a tangent line to the actual signal from the DC level to VREF(dc) level is used for derating value. See Figure 4 Illustration of tangent line for tIH.

Although for slow slew rates the total setup time might be negative (i.e. a valid input signal will not have reached VIH/IL(ac) at the time of the rising clock transition) a valid input signal is still required to complete the transition and reach VIH/IL(ac). For slew rates in between the values listed in above tIS/tIH derating values for DDR2-667, DDR2-800 and DDR2-1066 table, the derating values may be obtained by linear interpolation.

These values are typically not subject to production test. They are verified by design and characterization.

0.6	-	-	-	-	-	-	-	-	-10	-59	2	-47	14	-35	26	-23	38	-11
0.5	-	-	-	-	-	-	-	-	-	-	-24	-89	-12	-77	0	-65	12	-53
0.4	-	-	-	-	-	-	-	-	-	-	-	-	-52	-140	-40	-128	-28	-116

For all input signals the total tDS (setup time) and tDH (hold time) required is calculated by adding the data sheet tDS(base) and tDH(base) value to the ΔtDS and ΔtDH derating value respectively. Example: tDS (total setup time) = tDS(base) + ΔtDS.

Setup (tDS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VREF(dc) and the first crossing of VIH(ac)min. Setup (tDS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VREF(dc) and the first crossing of VIL(ac)max. If the actual signal is always earlier than the nominal slew rate line between shaded 'VREF(dc) to AC region', use nominal slew rate for derating value. See Figure 5 Illustration of nominal slew rate for tDS (differential DQS,/DQS ).

If the actual signal is later than the nominal slew rate line anywhere between shaded 'VREF(dc) to AC region', the slew rate of a tangent line to the actual signal from the AC level to DC level is used for derating value. See Figure 6 Illustration of tangent line for tDS (differential DQS,/DQS ).

Hold (tDH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL (dc)max and the first crossing of VREF(dc). Hold (tDH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(dc)min and the first crossing of VREF(dc). If the actual signal is always later than the nominal slew rate line between shaded 'DC level to VREF(dc) region', use nominal slew rate for derating value. See Figure 7 Illustration of nominal slew rate for tDH (differential DQS,/DQS ).

If the actual signal is earlier than the nominal slew rate line anywhere between shaded 'DC to VREF(dc) region', the slew rate of a tangent line to the actual signal from the DC level to VREF(dc) level is used for derating value. See Figure 8 Illustration of tangent line for tDH (differential DQS,/DQS ).

Although for slow slew rates the total setup time might be negative (i.e. a valid input signal will not have reached VIH/IL(ac) at the time of the rising clock transition) a valid input signal is still required to complete the transition and reach VIH/IL(ac). For slew rates in between the values listed in above DDR2-667, DDR2-800 and DDR2-1066 tDS/tDH derating with differential data strobe table, the derating values may be obtained by linear interpolation.

Power Down Mode Exit	L	H	H	X	X	X	X	X	X	X
			L	H	H	H				

H = High level, L = Low level, X = Don't care, BA=Bank Address

**Note1:** All DDR2 SDRAM commands are defined by states of /CS , /RAS , /CAS , /WE and CKE at the rising edge of the clock.

**Note2:** Bank addresses BA[1:0] determine which bank is to be operated upon. For (E)MRS BA selects an (Extended) Mode Register.

**Note3:** Burst reads or writes at BL = 4 can not be terminated or interrupted. See "Burst Interrupt" in section 8.5 for details.

**Note4:** VREF must be maintained during Self Refresh operation.

**Note5:** Self Refresh Exit is asynchronous.

**Note6:** The Power Down does not perform any refresh operations. The duration of Power Down Mode is therefore limited by the refresh requirements outlined in section 8.9.

## CKE Truth Table

Current State	CKE		Command (n) /RAS, /CAS, /WE, /CS	Action (n)	Notes
	n-1	n			
Power Down	L	L	X	Maintain power down	11,13,15
	L	H	DESELECT or NOP	Power down exit	4,8,11,13
Self Refresh	L	L	X	Maintain power down	11,15,16
	L	H	DESELECT or NOP	Self refresh exit	4,5,9,16
Bank Active	H	L	DESELECT or NOP	Active power down entry	4,8,10,11,13,
All Banks Idle	H	L	DESELECT or NOP	Power power down entry	4,8,10,11,13,
	H	L	REFRESH	Self refresh entry	6,9,11,13
	H	L	Refer to the command truth table		7

**Note1:** CKE (N) is the logic state of CKE at clock edge N; CKE (N-1) was the state of CKE at the previous clock edge.

**Note2:** Current state is the state of the DDR2 SDRAM immediately prior to clock edge N.

**Note3:** COMMAND (N) is the command registered at clock edge N, and ACTION (N) is a result of COMMAND (N).

**Note4:** All states and sequences not shown are illegal or reserved unless explicitly described elsewhere in this document.

**Note5:** On Self Refresh Exit DESELECT or NOP commands must be issued on every clock edge occurring during the tXSNR period. Read commands may be issued only after tXSRD (200 clocks) is satisfied.

**Note6:** Self Refresh mode can only be entered from the All Banks Idle state.

**Note7:** Must be a legal command as defined in the Command Truth Table.

**Note8:** Valid commands for Power Down Entry and Exit are NOP and DESELECT only.

**Note9:** Valid commands for Self Refresh Exit are NOP and DESELECT only.

**Note10:** Power Down and Self Refresh can not be entered while Read or Write operations, (Extended) Mode Register Set operations or Precharge operations are in progress. See section 8.9 "Power Down Mode" and section 8.3.7/8.3.8 "Self Refresh Entry Command/Self Refresh Exit Command" for a detailed list of restrictions.

**Note11:** tCKE<sub>min</sub> of 3 clocks means CKE must be registered on three consecutive positive clock edges. CKE must remain at the valid input level the entire time it takes to achieve the 3 clocks of registration. Thus, after any CKE transition, CKE may not transition from its valid level during the time period of tIS + 2 x tCK + tIH.

**Note12:** The state of ODT does not affect the states described in this table. The ODT function is not available during Self Refresh.

**Note13:** The Power Down does not perform any refresh operations. The duration of Power Down Mode is therefore limited by the refresh requirements outlined in section 8.9.

**Note14:** CKE must be maintained HIGH while the SDRAM is in OCD calibration mode.

**Note15:** "X" means "don't care (including floating around VREF)" in Self Refresh and Power Down. However ODT must be driven high or low in Power Down if the ODT function is enabled (Bit A2 or A6 set to "1" in EMR (1)).

**Note16:** VREF must be maintained during Self Refresh operation.

**Operative Command Table**

Current State	/CS	/R	/C	/W	Addr.	Command	Action
Idle	H	X	X	X	X	DESL	NOP

Any State Other than Listed above	H	H	X	X	X	X	X	Refer to command truth table

**Remark** H = High level, L = Low level, X = High or Low level (Don't care)

**Notes 1:** After CKE's low to high transition to exist self refresh mode. And a time of  $t_{RC}(\text{min})$  has to be Elapse after CKE's low to high transition to issue a new command.

**Notes 2:** CKE low to high transition is asynchronous as if restarts internal clock.

**Notes 3:** Power down and self refresh can be entered only from the idle state of all banks.

## Initialization

The following sequence is required for power-up and initialization and is shown in below Figure:

1. Apply power and attempt to maintain CKE below  $0.2 \times V_{DDQ}$  and  $ODT^*_1$  at a LOW state (all other inputs may be undefined.) Either one of the following sequence is required for Power-up.
  - A. The VDD voltage ramp time must be no greater than 200 mS from when VDD ramps from 300 mV to VDD min; and during the VDD voltage ramp,  $|V_{DD} - V_{DDQ}| \leq 0.3$  volts.  
VDD, VDDL and VDDQ are driven from a single power converter output  
VTT is limited to 0.95V max  
VREF tracks VDDQ/2  
 $V_{DDQ} \geq V_{REF}$  must be met at all times
  - B. Voltage levels at I/Os and outputs must be less than VDDQ during voltage ramp time to avoid DRAM latch-up. During the ramping of the supply voltages,  $V_{DD} \geq V_{DDL} \geq V_{DDQ}$  must be maintained and is applicable to both AC and DC levels until the ramping of the supply voltages is complete.  
Apply VDD/VDDL before or at the same time as VDDQ  
Apply VDDQ before or at the same time as VTT  
VREF tracks VDDQ/2  
 $V_{DDQ} \geq V_{REF}$  must be met at all times  
Apply VTT  
The VTT voltage ramp time from when VDDQ min is achieved on VDDQ to when VTT min is achieved on VTT must be no greater than 500 mS
2. Start Clock and maintain stable condition for 200  $\mu$ S (min.).
3. After stable power and clock (CLK,CLK ), apply NOP or Deselect and take CKE HIGH.
4. Wait minimum of 400 nS then issue precharge all command. NOP or Deselect applied during 400 nS period.
5. Issue an EMRS command to EMR (2). (To issue EMRS command to EMR (2), provide LOW to BA0, HIGH to BA1.)
6. Issue an EMRS command to EMR (3). (To issue EMRS command to EMR (3), provide HIGH to BA0 and BA1.)
7. Issue EMRS to enable DLL. (To issue DLL Enable command, provide LOW to A0, HIGH to BA0 and LOW to BA1. And A9=A8=A7=LOW must be used when issuing this command.)
8. Issue a Mode Register Set command for DLL reset. (To issue DLL Reset command, provide HIGH to A8 and LOW to BA0 and BA1.)
9. Issue a precharge all command.
10. Issue 2 or more Auto Refresh commands.
11. Issue a MRS command with LOW to A8 to initialize device operation. (i.e. to program operating parameters without resetting the DLL.)
12. At least 200 clocks after step 8, execute OCD Calibration (Off Chip Driver impedance adjustment).  
If OCD calibration is not used, EMRS to EMR (1) to set OCD Calibration Default (A9=A8=A7=HIGH) followed by EMRS to EMR (1) to exit OCD Calibration Mode (A9=A8=A7=LOW) must be issued with other operating parameters of EMR(1).
13. The DDR2 SDRAM is now ready for normal operation.

## Reset and Power up initialization sequence

## Mode Register Definition

### Mode Register Set Command (MRS)

The mode register stores the data for controlling the various operating modes of DDR2 SDRAM. It programs CAS Latency, burst length, burst sequence, test mode, DLL reset, Write Recovery (WR) and various vendor specific options to make DDR2 SDRAM useful for various applications. The default value in the Mode Register after power-up is not defined, therefore the Mode Register must be programmed during initialization for proper operation.

The DDR2 SDRAM should be in all bank precharge state with CKE already HIGH prior to writing into the mode register. The mode register set command cycle time (tMRD) is required to complete the write operation to the mode register. The mode register contents can be changed using the same command and clock cycle requirements during normal operation as long as all banks are in the precharge state. The mode register is divided into various fields depending on functionality. Burst length is defined by A[2:0] with options of 4 and 8 bit burst lengths. The burst length decodes are compatible with DDR SDRAM. Burst address sequence type is defined by A3, CAS Latency is defined by A[6:4]. The DDR2 does not support half clock latency mode. A7 is used for test mode. A8 is used for DLL reset. A7 must be set to LOW for normal MRS operation. Write recovery time WR is defined by A[11:9]. Refer to the table for specific codes.

**Note1:** WR (write recovery for Auto-precharge) min is determined by tCK(avg) max and WR max is determined by tCK(avg) min.  $WR[\text{cycles}] = \text{RU}\{ tWR[\text{nS}] / tCK(\text{avg})[\text{nS}] \}$ , where RU stands for round up. The mode register must be programmed to this value. This is also used with tRP to determine tDAL.

## Burst Type (A3)

Burst Length	Starting Address (A2 A1 A0)	Sequential Addressing (decimal)	Interleave Addressing (decimal)
4	x00	0123TTTT	0123TTTT
	x01	1230TTTT	1032TTTT
	x10	2301TTTT	2301TTTT
	x11	3012TTTT	3210TTTT
8	000	01234567	01234567
	001	12305674	10325476
	010	23016745	23016745
	011	30127456	32107654
	100	45670123	45670123
	101	56741230	54761032
	110	67452301	67452301
	111	74563012	76543210

## Write Recovery

WR (Write Recovery) is for Writes with Auto-Precharge only and defines the time when the device starts pre-charge internally. WR must be programmed to match the minimum requirement for the analogue tWR timing.

## Power-Down Mode

Active power-down (PD) mode is defined by bit A12. PD mode allows the user to determine the active power down mode, which determines performance vs. power savings. PD mode bit A12 does not apply to precharge power down mode. When bit A12 = 0, standard Active Power-down mode or ‘fast-exit’ active power down mode is enabled. The tXARD parameter is used for ‘fast-exit’ active power-down exit timing. The DLL is expected to be enabled and running during this mode. When bit M12 = 1, a lower power active power down mode or ‘slow-exit’ active power-down mode is enabled. The tXARDS parameter is used for ‘slow-exit’ active power-down exit timing. The DLL can be enabled, but ‘frozen’ during active power down mode since the exit to READ command timing is relaxed. The power difference expected between PD ‘normal’ and PD ‘low-power’ mode is defined in the IDD table.

## Extend Mode Register EMR1

The EMR1 stores the data for enabling or disabling the DLL, output driver strength, additive latency, ODT, DQS disable, OCD program. The default value of the EMR1 is not defined, therefore the EMR1 must be programmed during initialization for proper operation. The DDR2 SDRAM should be in all bank precharge with CKE already high prior to writing into the EMR1. The mode register set command cycle time (tMRD) must be satisfied to complete the write operation to the extended MR1. EMR1 contents can be changed using the same command and clock cycle requirements during normal operation as long as all banks are in the precharge state. A0 is used for DLL enable or disable. A1 is used for enabling a reduced strength output driver. A[5:3] determines the additive latency, A[9:7] are used for OCD control, A10 is used for DQS disable. A2 and A6 are used for ODT setting.

**Note1:** A11 default is “0” RDQS disabled.

**Note2:** Optional for DDR2-667, mandatory for DDR2-800 and DDR2-1066.

**Note3:** When Adjust mode is issued, AL from previously set value must be applied.

**Note4:** After setting to default, OCD calibration mode needs to be exited by setting A9-A7 to 000. Refer to the section 8.2.3 for detailed information.

**Note5:** Output disabled - DQs, LDQS, LDQS , UDQS, UDQS . This feature is used in conjunction with DIMM IDD measurements when IDDQ is not desired to be included.

### DLL Enable/Disable

The DLL must be enabled for normal operation. DLL enable is required during power-up initialization, and upon returning to normal operation after having the DLL disabled. The DLL is automatically disabled when entering Self Refresh operation and is automatically re-enabled and reset upon exit of Self Refresh operation. Any time the DLL is enabled (and subsequently reset), 200 clock cycles must occur before a Read command can be issued to allow time for the internal clock to be synchronized with the external clock. Failing to wait for synchronization to occur may result in a violation of the tAC or tDQSCK parameters.

### Extend Mode Register EMR2

The EMR 2 controls refresh related features. The default value of the EMR 2 is not defined, therefore the EMR 2 must be programmed during initialization for proper operation.

The DDR2 SDRAM should be in all bank precharge state with CKE already high prior to writing into the EMR 2. The mode register set command cycle time (tMRD) must be satisfied to complete the write operation to the EMR 2. Mode register contents can be changed using the same command and clock cycle requirements during normal operation as long as all banks are in the precharge state.

**Note1:** The rest bits in EMR 2 is reserved for future use and all bits in EMR 2 except A7, BA0 and BA1 must be programmed to 0 when setting the extended mode register 2 during initialization.

**Note2:** When DRAM is operated at 85°C < TCASE ≤ 95°C the extended Self Refresh rate must be enabled by setting bit A7 to “1” before the Self Refresh mode can be entered.

### Extend Mode Register EMR3

No function is defined in extended mode register 3. The default value of the EMR 3 is not defined, therefore the EMR 3 must be programmed during initialization for proper operation.

**Note1:** All bits in EMR 3 except BA0 and BA1 are reserved for future use and must be set to 0 when programming the EMR 3.

### On-Die Termination (ODT)

ODT (On-Die Termination) is a new feature on DDR2 components that allows a DRAM to turn on/off termination resistance for each UDQ, LDQ, UDQS, LDQS, UDM and LDM signal via the ODT control pin for x16 configuration, where UDQS and LDQS are terminated only when enabled in the EMRS(1) by address bit A10 = 0.

The ODT feature is designed to improve signal integrity of the memory channel by allowing the DRAM controller to independently turn on/off termination resistance for any or all DRAM devices. The ODT function can be used for all active and standby modes. ODT is turned off and not supported in Self- Refresh mode.

### ODT Function

Switch sw1 or sw2 is enabled by the ODT pin. Selection between sw1 or sw2 is determined by “Rtt (nominal)” in EMRS(1) address bits A6 & A2. Target  $R_{tt} = 0.5 * R_{val1}$  or  $0.5 * R_{val2}$ . The ODT pin will be ignored if the EMRS(1) is programmed to disable ODT.

**Package Description: 84Ball-FBGA**

**Solder ball: Lead free (Sn-Ag-Cu)**
